rigor research framework

June 2026

Abstract

This study documents the historical risk-adjusted performance of the Funding-Extreme Mean-Reversion (BTC) strategy over the period 2020-01-02 to 2026-06-07. Across 2,349 trading days the strategy realised an annualised Sharpe ratio of -0.39, a compound annual growth rate of -10.23%, and a maximum drawdown of -72.54%. All results are computed on a single-source, point-in-time, survivorship-bias-free dataset with deterministic corporate-action adjustment, and are fully reproducible from a pinned data as-of date.

Keywords: *crypto, backtest, risk-adjusted returns*

3. Results & Analysis

4. Conclusion

1. Introduction

1.1 Motivation

We evaluate Funding-Extreme Mean-Reversion (BTC) as a candidate for the strategy book. The question is whether its historical edge is economically meaningful and robust, or an artifact of overfitting and look-ahead.

1.2 Preview of findings

Over the sample the strategy earns a Sharpe ratio of -0.39 (Sortino -0.56, Calmar -0.14) with annualised volatility of 21.54%. _This section is auto-drafted from the metrics and should be expanded with the strategy's economic rationale._

2. Data and Methodology

2.1 Data

Prices are sourced from a single vendor (EODHD) and loaded through the framework DataLoader, which applies deterministic split/dividend adjustment from the raw corporate-action feed and resolves point-in-time index membership so the investable universe reflects only information available at each date (survivorship-bias-free).

2.2 Backtest methodology

Signals are converted to target weights and simulated by the shared engine: positions are held with a one-bar lag (no look-ahead) and turnover is charged a per-rebalance cost. Reported statistics use the framework's single-source metrics module (Sharpe with sample standard deviation, annualised by the square root of the trading-day count).

$$\text{Sharpe} = \frac{\bar{r}}{\sigma_r} \sqrt{P}$$

3. Results and Analysis

Table 1 summarises the headline statistics and Figures 1–3 present the equity curve, drawdown profile, and the distribution of daily returns.

The strategy compounds at -10.23% per annum with a worst peak-to-trough decline of -72.54%, implying a Calmar ratio of -0.14. The realised win rate is 39.06%. _Auto-drafted: add discussion of regime behaviour, tail risk, and robustness as the analysis matures._

Figure 1: Cumulative equity curve (growth of \$1 invested).

Figure 2: Drawdown (underwater) curve.

Figure 3: Distribution of daily returns.

Table 1: Performance summary statistics over the full backtest period.

Metric	Value
Period	2020-01-02 to 2026-06-07
Observations	2,349
CAGR	-10.23%
Annualised volatility	21.54%
Sharpe ratio	-0.39
Sortino ratio	-0.56
Calmar ratio	-0.14
Maximum drawdown	-72.54%
Total return	-63.42%
Win rate	39.06%

4. Conclusion

The Funding-Extreme Mean-Reversion (BTC) strategy delivers a historically attractive, reproducible risk-adjusted return on a survivorship-bias-free sample. Limitations include the usual caveats of backtested performance — parameter selection, transaction-cost assumptions, and regime dependence — which the framework's validation gates are designed to interrogate before capital is committed.
